[A FRUSTRAÇÃO] Gasto Calórico para emagrecer? NÃO É BEM ASSIM

Donelly 2003

ORIGINAL INVESTIGATION

Effects of a 16-Month Randomized Controlled Exercise Trial on Body Weight and Composition in Young, Overweight Men and Women

The Midwest Exercise Trial

Fennessey, PhD; Bakary Sonko, PhD; Teresa Sharp, MS; John M. Jakicic, PhD; Steven N. Blair, PED; Zung V. Tran, PhD; Matthew Mayo, PhD; Cheryl Gibson, PhD; Richard A. Washburn, PhD

Background: In light of the current obesity epidemic, treatment models are needed that can prevent weight gain or provide weight loss. We examined the long-term effects of a supervised program of moderate-intensity exercise on body weight and composition in previously sedentary, overweight and moderately obese men and women. We hypothesized that a 16-month program of verified exercise would prevent weight gain or provide weight loss in the exercise group compared with controls.

Methods: This was a randomized controlled efficacy trial. Participants were recruited from 2 midwestern universities and their surrounding communities. One hundred thirty-one participants were randomized to exercise or control groups, and 74 completed the intervention and all laboratory testing. Exercise was supervised, and the level of energy expenditure of exercise was measured. Controls remained sedentary. All participants maintained ad libitum diets.

Results: Exercise prevented weight gain in women and produced weight loss in men. Men in the exercise group had significant mean±SD decreases in weight (5.2±4.7 kg), body mass index (calculated as weight in kilograms divided by the square of height in meters) (1.6±1.4), and fat mass (4.9±4.4 kg) compared with controls. Women in the exercise group maintained baseline weight, body mass index, and fat mass, and controls showed significant mean±SD increases in body mass index (1.1±2.0), weight (2.9±5.5 kg), and fat mass (2.1±4.8 kg) at 16 months. No significant changes occurred in fat-free mass in either men or women; however, both had significantly reduced visceral fat.

Conclusions: Moderate-intensity exercise sustained for 16 months is effective for weight management in young adults.

The effects of high-intensity intermittent exercise training on fat loss and fasting insulin levels of young women

EG Trapp[1], DJ Chisholm[2], J Freund[1] and SH Boutcher[1]

[1]Faculty of Medicine, University of New South Wales, Sydney, New South Wales, Australia and [2]Garvan Institute, Sydney, New South Wales, Australia

Objective: To determine the effects of a 15-week high-intensity intermittent exercise (HIIE) program on subcutaneous and trunk fat and insulin resistance of young women.
Design and procedures: Subjects were randomly assigned to one of the three groups: HIIE ($n=15$), steady-state exercise (SSE; $n=15$) or control (CONT; $n=15$). HIIE and SSE groups underwent a 15-week exercise intervention.
Subjects: Forty-five women with a mean BMI of $23.2 \pm 2.0\,kg\,m^{-2}$ and age of 20.2 ± 2.0 years.
Results: Both exercise groups demonstrated a significant improvement ($P<0.05$) in cardiovascular fitness. However, only the HIIE group had a significant reduction in total body mass (TBM), fat mass (FM), trunk fat and fasting plasma insulin levels. There was significant fat loss ($P<0.05$) in legs compared to arms in the HIIE group only. Lean compared to overweight women lost less

PRACTICAL APPLICATIONS

The results of this study suggest that the cardiovascular strain elicited by a single session of low-volume, high-intensity intermittent burpees may be sufficient to confer cardiorespiratory and metabolic adaptations equivalent to those reported in studies using SIC. These vigorous, or near maximal, acute responses complement previously reported findings of increased skeletal muscle oxidative capacity, maximal oxygen uptake, and endurance performance after training programs using traditional aerobic training modalities. The programming of HIT by strength and conditioning professionals is becoming more frequent as clients seek alternative methods that enhance fitness with relatively little time commitment. Inclusion of high-intensity whole-body calisthenics performed in the manner described in this study provides a vigorous exercise stimulus in a very short time. Such a program may be well suited to both recreational and competitive athletes seeking rapid improvements in fitness with minimal time commitment.

Extremely low volume, whole-body aerobic–resistance training improves aerobic fitness and muscular endurance in females

Gill McRae, Alexa Payne, Jason G.E. Zelt, Trisha D. Scribbans, Mary E. Jung, Jonathan P. Little, and Brendon J. Gurd

Abstract: The current study evaluated changes in aerobic fitness and muscular endurance following endurance training and very low volume, whole-body, high-intensity, interval-style aerobic–resistance training. Subjects' enjoyment and implementation intentions were also examined prior to and following training. Subjects (22 recreationally active females (20.3 ± 1.4 years)) completed 4 weeks of exercise training 4 days per week consisting of either 30 min of endurance treadmill training (~85% maximal heart rate; $n = 7$) or whole-body aerobic–resistance training involving one set of 8×20 s of a single exercise (burpees, jumping jacks, mountain climbers, or squat thrusts) separated by 10 s of rest per session ($n = 7$). A third group was assigned to a nontraining control group ($n = 8$). Following training, $\dot{V}O_{2peak}$ was increased in both the endurance (~7%) and interval (~8%) groups ($p < 0.05$), whereas muscle endurance was improved ($p < 0.05$) in the interval group (leg extensions, +40%; chest presses, +207%; sit-ups, +64%; push-ups, +135%; and back extensions, +75%). Perceived enjoyment of, and intentions to engage in, very low volume, high-intensity, whole-body interval exercise were both increased following training ($p < 0.05$). No significant changes were observed for any variable in the control (nontraining) group. These data demonstrate that although improvements in cardiovascular fitness are induced by both endurance and extremely low volume interval-style training, whole-body aerobic–resistance training imparted addition benefit in the form of improved skeletal muscle endurance.

Conclusion

In recreationally active females, four weeks (4 days·week^{-1}) of very low volume, whole-body, high-intensity interval training elicited similar improvements in aerobic capacity as endurance training, but resulted in the additional benefit of increased muscular endurance. Additional research is required to examine the contributing factors and cellular pathways (presumably in skeletal muscle) that mediate these adaptations. Further studies may also wish to examine whether this type of exercise can improve markers of health in individuals at risk for developing inactivity-related diseases such as cardiovascular disease and type 2 diabetes. Given the minimal requirement for exercise equipment and the low time commitment, studies exploring adaptations and adherence to this whole-body, high-intensity interval training protocol could facilitate application to home-based exercise programs. This could have widespread impact for encouraging exercise participation and resultant improvements in health.

Conclusion

In summary, we report that a SIT protocol involving 3 minutes of intense intermittent exercise per week, within a total time commitment of 30 minutes, is as effective as 150 minutes per week of moderate-intensity continuous training for increasing insulin sensitivity, cardiorespiratory fitness and skeletal muscle mitochondrial content in previously inactive men. This investigation represents the longest comparison of SIT and MICT to date and demonstrates the efficacy of brief, intense exercise to improve indices of cardiometabolic health. While SIT is clearly a potent stimulus to elicit physiological adaptations, this type of exercise requires a very high level of motivation and is clearly not suited for everyone. Future studies should examine the potential for interval training protocols that involve relatively intense but not "all out" efforts to elicit changes like that shown in the present study. Considering that a large number
